

Placebo Treatment Refuter

Placebo Treatment refutation asks: What happens to the estimated causal effect when we replace the true treatment variable with an independent random variable? (Hint: the effect should go to zero)

```
>>> res_placebo=model.refute_estimate(identified_estimand, estimate,  
>>>     method_name="placebo_treatment_refuter", show_progress_bar=True, placeb  
>>> print(res_placebo)
```
